

Instructions:

- You are given the question sheet and 4 sheets for your answers. The problems are 4.
- Before you start, write on the top of each sheet (1) your full name, (2) your student ID (*matricola*) and (3) the sheet number (1, 2, 3, and 4).
- If you use additional sheets as rough draft (*brutta*) for calculations, etc., you must hand it, along with the rest of the exam. You can keep the question sheet.
- Hand in the sheets in order **without attaching the sheets with each other**.
- When your pages are full, you can ask for extra pages; make sure that you also write there your name, student id, and the sheet number (5, 6, etc.). You must hand all the sheets that you receive.
- The rooms are small so it may be tempting to copy. Note that if we catch you copying in any way (copying from another student, using your phone, etc.) you will be automatically disqualified.

Problem 1

Consider the following scenario. Due to large-scale flooding in a region, paramedics have identified a set of n injured people distributed across the region who need to be rushed to hospitals. There are k hospitals in the region, and each of the n people needs to be brought to a hospital that is within a half-hour's driving time of their current location (so different people will have different options for hospitals, depending on where they are right now). At the same time, one doesn't want to overload any one of the hospitals by sending too many patients its way. The paramedics are in touch by cell phone, and they want to collectively work out whether they can choose a hospital for each of the injured people in such a way that the load on the hospitals is balanced: Each hospital receives at most $\lceil n/k \rceil$ people.

- (a) Give a polynomial-time algorithm that takes the given information about the people's locations and determines **whether** this is possible.
- (b) Discuss its time complexity.

Problem 2

We are given a rod of integer length L . We assume that a rod of integer length $0 \leq l \leq L$ has a known value $v(l)$. The problem is to find the best way of cutting the rod, such that the sum of the values of the resulting rods is maximised.

- (a) Show a dynamic programming algorithm that solves the problem.
- (b) Provide the pseudo-code of an efficient implementation of the algorithm and discuss its time complexity.

Problem 3

Suppose you're helping to organize a summer sports camp, and the following problem comes up. The camp is supposed to have at least one counselor who's skilled at each of the n sports covered by the camp (baseball, volleyball, and so on). They have received job applications from c potential counselors. For each of the n sports, there is some subset of the c applicants qualified in that sport. The question is: For a given number $k < c$, is it possible to hire at most k of the counselors and have at least one counselor qualified in each of the n sports? We'll call this the **EfficientRecruiting Problem**. Show that **EfficientRecruiting** is NP-complete.

Problem 4

Consider the directed Max-Cut problem: given a directed graph $G = (V, A)$ with non-negative weights w_{ij} on the arcs, the problem is to find a cut $(S, V \setminus S)$ of the vertices, such that $\sum_{(i,j) \in A, i \in S, j \notin S} w_{ij}$ is maximized.

Show a randomized algorithm that achieves an expected approximation ratio of $\frac{1}{2}$.
